## **Practical-8**

# Study of Docker swarm and Deployment of ML project in swarm network

The objective of this lab is to understand Docker Swarm, a container orchestration tool, and deploy a machine learning project in a Swarm network using three Linux host systems.

### **Prerequisites:**

- Three Linux host systems (e.g., Ubuntu)
- Docker installed on each host (follow the installation steps in the previous response)
- Basic understanding of Docker and machine learning concepts

#### Lab Setup:

- Assign unique hostnames and IP addresses to each Linux host.
- Ensure that the hosts can communicate with each other over the network.

#### Lab Steps:

#### Step 1: Initialize Docker Swarm

```
[(base) arthjani@Arths-MacBook-Air ~ % docker swarm init
Swarm initialized: current node (lodicoyslsxlkbdudfmyldtxd) is now a manager.

To add a worker to this swarm, run the following command:

docker swarm join --token SWMTKN-1-4awek4wu5rq4f88buor43koettw2t2apm86syl1f69to6t6rwn-5biixwoh
jvujlduq88qznarod 192.168.65.3:2377

To add a manager to this swarm, run 'docker swarm join-token manager' and follow the instructions.
```

#### **Step 2:** Join Worker Nodes

```
(base) arthjani@Arths-MacBook-Air ~ % docker swarm join-token manager
To add a manager to this swarm, run the following command:

docker swarm join --token SWMTKN-1-4awek4wu5rq4f88buor43koettw2t2apm86syl1f69to6t6rwn-ace954sh iprnm6z@e54u4vxi7 192.168.65.3:2377

(base) arthjani@Arths-MacBook-Air ~ % docker info --format '{{.Swarm.NodeAddr}}'
192.168.65.3
(base) arthjani@Arths-MacBook-Air ~ %
```

Step 3: Deploy a ML Model as a Service

Create a Docker Compose file (e.g., `ml\_app.yml`) with the following content

```
      V STREAM
      □ Pland Pland

      Image: model.h5
      2

      Image: model # Specify the image name here
      4

      Image: model # Specify the image name here
      5

      Image: model # Specify the image name here
      6

      Image: model # Specify the image name here
      9

      Image: model # Specify the image name here
      10
```

#### Step 4: Deploy the Service On the manager node, deploy the ML project as a service

```
PS D:\Desktop\stream> docker stack deploy -c ml_app.yml ml_stack
Creating network ml_stack_default
Creating service ml_stack_ml-app
```

#### **Step 5: Verify the Deployment Check the status of the deployed service:**

```
PS D:\Desktop\stream> docker service ls

ID NAME MODE REPLICAS IMAGE PORTS

i6ci69j@ud96 ml_stack_ml-app replicated 0/3 model:latest *:8080->8080/tcp
```

Step 6: Access the ML Project You can access the ML project on any of the worker nodes using their IP addresses and port 8080 (the port we exposed in the Compose file).

Using https://192.168.1.2:8080 we can access the model

Step 7: Scaling Experiment with scaling the service up or down to see how Docker Swarm manages

the replicas.

Step 8: Removing the Stack When done, you can remove the stack

PS D:\Desktop\stream> docker stack rm ml\_stack
Removing service ml\_stack\_ml-app
Removing network ml\_stack\_default

Step 9: Leave Swarm On worker nodes, leave the Swarm when you're finished

PS D:\Desktop\stream> docker swarm leave --force Node left the swarm.

Step 10: Shut Down Shut down all host systems.

PS D:\Desktop\stream> sudo shutdown -h now
